## Introduction

This work will present data analysis from a research that studied the enchancer's at IGF2 differential methylation association with abnormal dopamine synthesis in major psychosis (Pai et al., 2019).

Our samples were taken from the prefrontal cortex isolated neurons in schizophrenia and bipolar disorder.

Study analysed data from individuals diagnosed with schizophrenia, bipolar disorder and controls (29, 26 and 27 individuals, respectively). In the analysis study controlled for age, sex, post-mortem interval, genetic ancestry (determined by genotyping the same individuals).

### Experiment design

The experiment design was multi-omics study with 55 cases (with schizophrenia or bipolar disorder) and 27 controls.

### Objective of the research

According to authors, schizophrenia and bipolar disorder have got characteristic of periods of psychosis. The main objective of the research was to gather epigenomic profiling data to get a more accurate model of neuronal dysregulation in diseases with periods of psychosis.

#### Biological targets of the research

Researchers intended to look for specific patters of DNA methylation in isolated neurons from the frontal cortex of individuals that had diseases.

- IGF2 insulin growth factor 2 protein
- *IGF2* IGF2 gene
- Igf2 enhancer of IGF2
- TH tyrosine hydroxylase protein
- dopamine a neuromodulatory molecule
- psychosis an abnormal condition of the mind that results in difficulties determining what is real and what is not real

### Results received

Authors found a strong association between methylation of Igf2 and TH synthesis. TH is the bottleneck enzyme that is responsible for dopamine synthesis. If enhancer Igf2 is hypomethylated, levels of TH are higher, which determines the higher production of dopamine. Apparently, dopamine is responsible for psychosis in the mental disorders of interest.

#### Additional information

Schizophrenia and bipolar disorder patients are consistently hypomethylated at IGF2 locus when compared to controls. This locus remained significantly hypomethylated even after accounting lifestyle-related variables of smoking and anti-psychotic use.

The reaction chain of interest of the research (upward arrows show elevated expression or synthesis of the protein, product, or effect):

Hypomethylation of  $Igf2 \rightarrow \uparrow IGF2 \rightarrow \uparrow TH \rightarrow \uparrow dopamine \rightarrow \uparrow psychosis$ 

# Data preparation

```
sample_keys <- read.csv('../data/GSE112179.csv')
colnames(sample_keys)[5] <- tolower(colnames(sample_keys)[5])
length(sample_keys$donor)</pre>
```

## [1] 100

```
length(unique(sample_keys$donor))
```

## [1] 82

Sample keys heading is made of the following columns names:

- *id* an identifier of the sample
- sentrix\_id Illumina's Sentrix BeadChip identifier (13 different values) (National Institutes of Health, n.d.)
- sentrix\_row row number in the Sentrix array
- sentrix\_col column number in the Sentrix array
- basename sample identifier in the research (joined values in a format: [id]\_[sentrix\_id]\_R0[sentrix\_row]C0[sentrix\_id])
- tissue bank id an identifying number of the tissue bank from which the sample was taken
- tissue bank the literal identifier of the tissue bank
- $\bullet~$  tissue a tissue type from which the sample was taken
- *cell\_type* a cell type found in the sample
- donor an integer number that identifies the donor of the sample (82 unique values)

As it was noted in the article, there were 100 records in the sample keys dataset.
